

Solar Physics: Importance, Current Understanding and 'Yet Unanswered' Problems Prabir Kumar Mitra

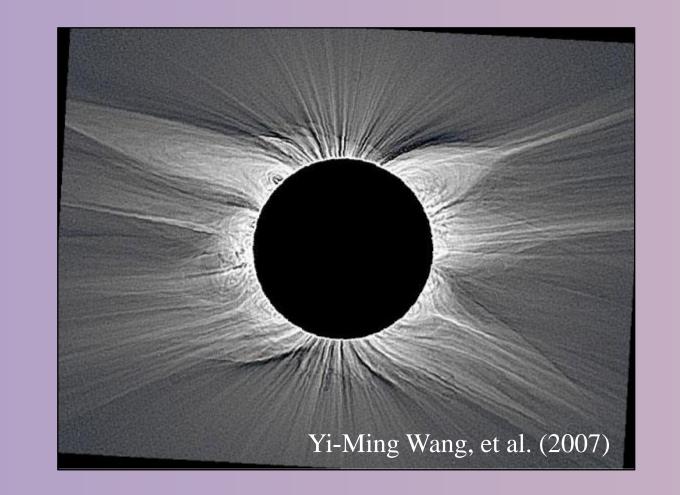

Udaipur Solar Observatory, Physical Research Laboratory

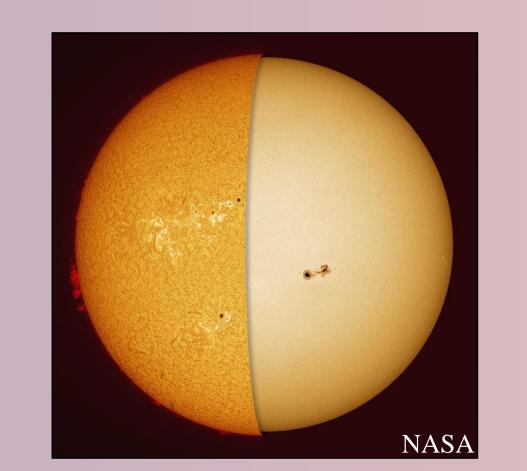

Why do we need the Sun?

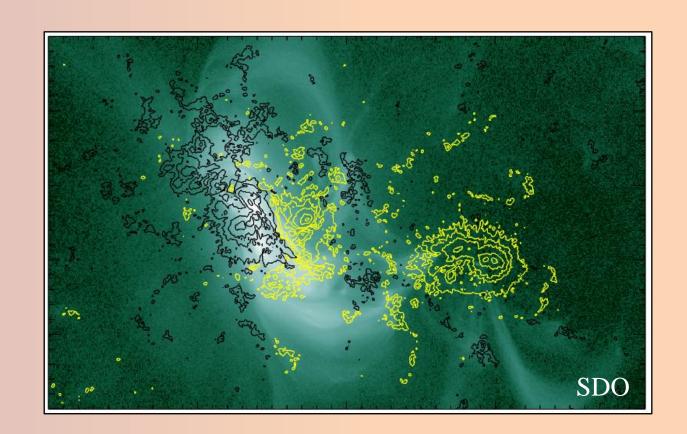

- Provides the most essential ingredient for life: energy (light and heat).
- Being the nearest star to us, it gives us the best opportunities to understand main sequence stars in general.
- It produces a natural laboratory for studying plasma physics.

"We should study the Sun because it is beautiful."- Dr. Arvind Bhatnagar

Different atmospheric layers of the Sun

Sun as a star

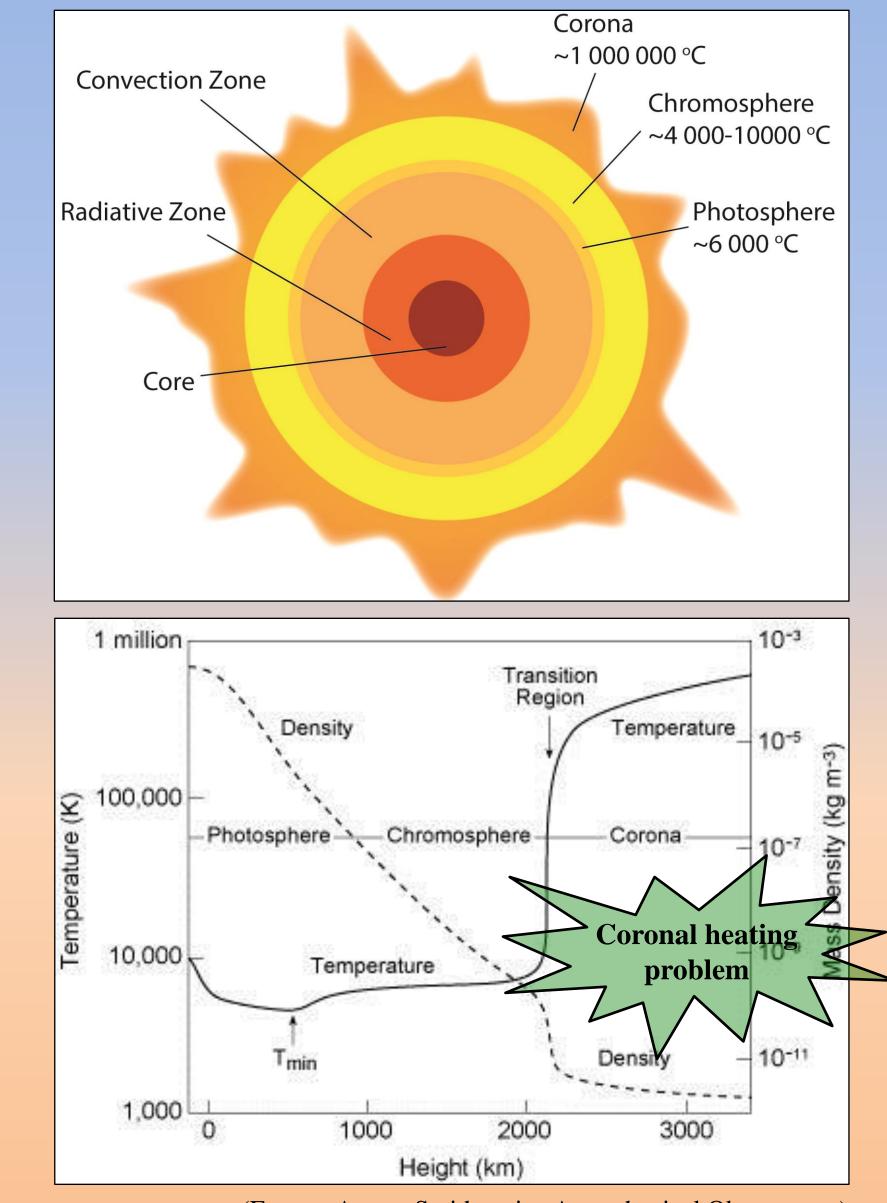

Radius: ~696000 km (~109 R_{F})

Mass: $\sim 2 \times 10^{30}$ kg ($\sim 333000 \text{ M}_{\text{F}}$)

G-type main sequence star

Age: ~4.6 billion years

Corona

• Outermost layer of the solar atmosphere \Box Density is very low: ~10¹⁵ particles/m³ □ Temperature is very high: few million K □ Highly structured magnetic field

Chromosphere

□ Second layer of the solar atmosphere • Observed in reddish color during the solar eclipse □ Filaments are observed in chromospheric images

Photosphere

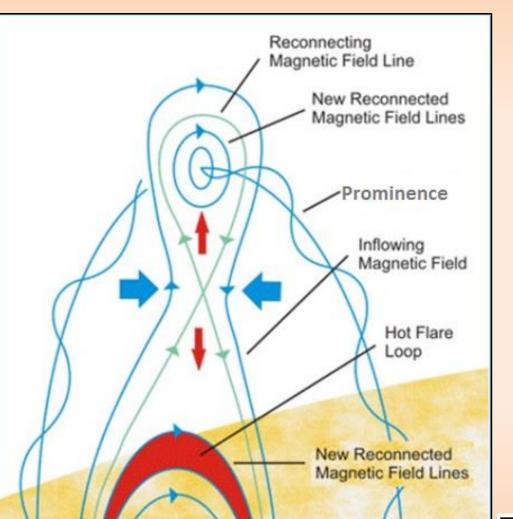

□ So called "surface" of the Sun. □ Most of the intense light from the Sun comes from this region □ Sunspots are observed in photospheric images

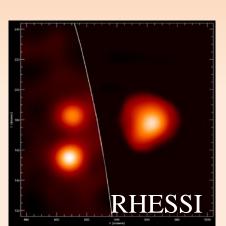

Sunspots are connected by magnetic loops that extend up to the corona. In corona, because of 'Alfvén's frozen in condition'. magnetic field gets embedded into the plasma body. Emission from these trapped plasma makes coronal loops visible.

(Eugene Avrett, Smithsonian Astrophysical Observatory)

Standard Flare Model

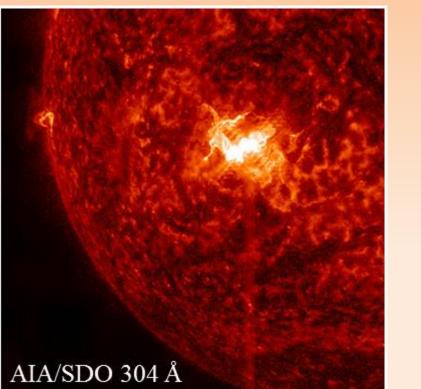

Based on the pioneering works of Carmichael 1964, Sturrock 1966, Hirayama 1974, Kopp & Pneuman 1976. Therefore, this model is also called 'CSHKP model'.

Active Sun

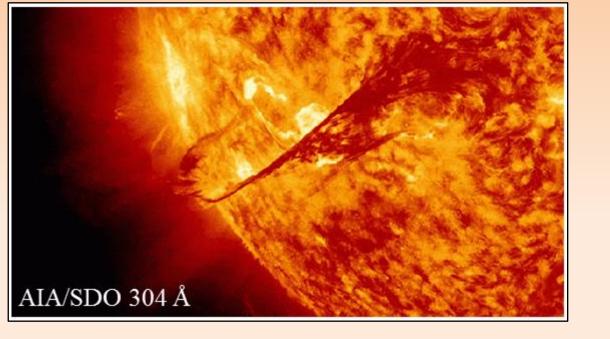

Flare

□ Sudden, localized enhanced brightness observed in the solar atmosphere \Box Energy released during a flare: 10^{27} to 10³² erg: most energetic in the solar system

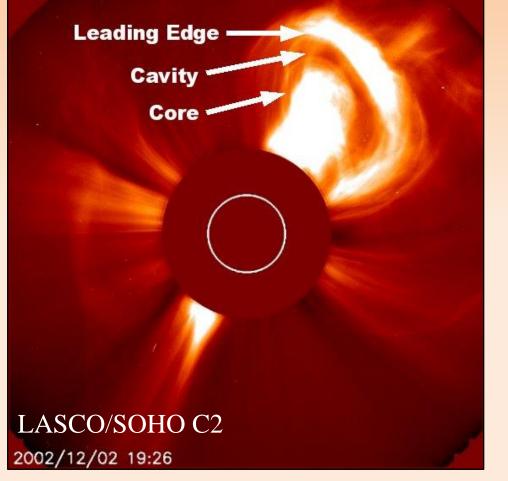

□ Magnetic reconnection is believed to be the source of the energy released during a flare.

During a flare, electro-magnetic radiation is observed across the entire e-m spectrum. Lifetime of a flare: few minutes to several hours.

Filament/Prominence eruption □ Filaments are dark, thread-like structures observed in the chromospheric images of the Sun.

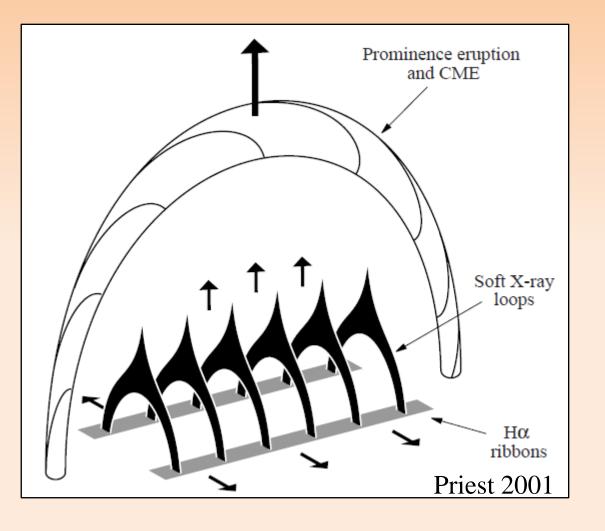

These are structures composed of relatively cool, dense plasma in association with magnetic field. □ Successful eruption of a filament leads to the formation of 'coronal mass ejections' (CMEs).

Coronal Mass Ejection (CME)

□ Release of huge amount of plasma and magnetic field in the interplanetary medium from the solar corona

□ When CMEs interact with the Earth's magnetosphere, the effects are called 'space weather'.

When a filament achieves eruptive motion, it induces inflow of surrounding magnetic field causing reconnection between them. As a result, flare happens. Erupting filament constitutes a CME.

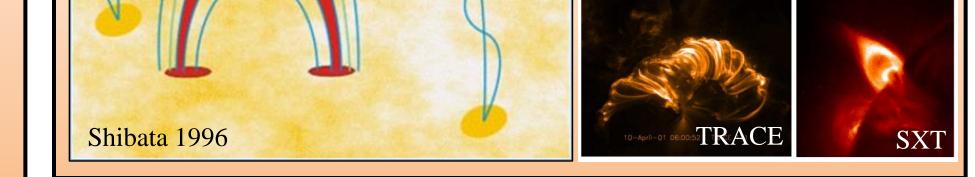

T=26.6 MK EM= 3.6×10^{48} cm⁻³ δ = 5.1

E_B=24.7 keV

T=27.9 MK EM= $5.0 \times 10^{48} \text{ cm}^{-3}$ $\delta = 3.4$

E_B=25.2 keV

□ Filament eruptions, flares, and CMEs are observed to be intrinsically related and believed to be different manifestations of same physical mechanism: magnetic reconnection.

Open Questions

- What causes coronal temperature to be so high? How is it sustained? What are the exact formation mechanisms of sunspots and active regions?
- What is the exact morphology of filaments/prominences?
- How a flux rope eruption is triggered?

 \circ etc.

Not all flares are eruptive. What are the factors that determine whether a flare will be eruptive or confined?

Circular ribbon flares usually contain a pre-existing coronal null point. How null points evolve during a circular ribbon flare is still not known. There is no theoretical model that can explain magnetic reconnection properly.

Magnetic energy is released in the form of heat and particle acceleration during magnetic reconnection. The exact partition between thermal and non-thermal energy is not yet formulated.
